1 Asn1 User's Guide

The *Asn1* application contains modules with compile-time and run-time support for ASN.1.

1.1 Asn1

1.1.1 Introduction

Features

The *Asn1* application provides:

- An ASN.1 compiler for Erlang, which generates encode and decode functions to be used by Erlang programs sending and receiving ASN.1 specified data.
- Run-time functions used by the generated code.
- The supported encoding rules are:
 - Basic Encoding Rules (*BER*)
 - Distinguished Encoding Rules (*DER*), a specialized form of BER that is used in security-conscious applications.
 - Packed Encoding Rules (*PER*) both the aligned and unaligned variant.

Overview

ASN.1 (Abstract Syntax Notation 1) is a formal language for describing data structures to be exchanged between distributed computer systems. The purpose of ASN.1 is to have a platform and programming language independent notation to express types using a standardized set of rules for the transformation of values of a defined type, into a stream of bytes. This stream of bytes can then be sent on a communication channel set up by the lower layers in the stack of communication protocols e.g. TCP/IP or encapsulated within UDP packets. This way, two different applications written in two completely different programming languages running on different computers with different internal representation of data can exchange instances of structured data types (instead of exchanging bytes or bits). This makes programming faster and easier since no code has to be written to process the transport format of the data.

To write a network application which processes ASN.1 encoded messages, it is prudent and sometimes essential to have a set of off-line development tools such as an ASN.1 compiler which can generate the encode and decode logic for the specific ASN.1 data types. It is also necessary to combine this with some general language-specific runtime support for ASN.1 encoding and decoding.

The ASN.1 compiler must be directed towards a target language or a set of closely related languages. This manual describes a compiler which is directed towards the functional language Erlang. In order to use this compiler, familiarity with the language Erlang is essential. Therefore, the runtime support for ASN.1 is also closely related to the language Erlang and consist of a number of functions, which the compiler uses. The types in ASN.1 and how to represent values of those types in Erlang are described in this manual.

The following document is structured so that the first part describes how to use ASN.1 compiler, and then there are descriptions of all the primitive and constructed ASN.1 types and their representation in Erlang,

Prerequisites

It is assumed that the reader is familiar with the ASN.1 notation as documented in the standard definition [1] which is the primary text. It may also be helpful, but not necessary, to read the standard definitions [1] [2] [3] [4].

1.1 Asn1

A very good book explaining those reference texts is [], free to download at <http://www.oss.com/asn1/dubuisson.html>.

Capability

This application covers all features of ASN.1 up to the 1997 edition of the specification. In the 2002 edition of ASN.1 a number of new features were introduced of which some are supported while others are not. For example the ECN (Encoding Control Notation) and XML notation are still unsupported. Though, the other features of the 2002 edition are fully or partly supported as shown below:

- Decimal notation (e.g., "1.5e3") for REAL values. The NR1, NR2 and NR3 formats as explained in ISO6093 are supported.
- The RELATIVE-OID type for relative object identifiers are fully supported.
- The subtype constraint (CONTAINING/ENCODED BY) to constrain the content of an octet string or a bit string is parsed when compiling, but no further action is taken. This constraint is not a PER-visible constraint.
- The subtype constraint by regular expressions (PATTERN) for character string types is parsed when compiling, but no further action is taken. This constraint is not a PER-visible constraint.
- Multiple-line comments as in C, /* . . . */ , are supported.

It should also be added here that the encoding formats supported are *BER*, *DER*, *PER aligned basic* variant and *PER unaligned basic* variant.

1.1.2 Getting Started with Asn1

A First Example

The following example demonstrates the basic functionality used to run the Erlang ASN.1 compiler.

First, create a file called `People.asn` containing the following:

```
People DEFINITIONS IMPLICIT TAGS ::=
BEGIN
EXPORTS Person;

Person ::= [PRIVATE 19] SEQUENCE {
    name PrintableString,
    location INTEGER {home(0),field(1),roving(2)},
    age INTEGER OPTIONAL }
END
```

This file (`people.asn`) must be compiled before it can be used. The ASN.1 compiler checks that the syntax is correct and that the text represents proper ASN.1 code before generating an abstract syntax tree. The code-generator then uses the abstract syntax tree in order to generate code.

The generated Erlang files will be placed in the current directory or in the directory specified with the `{outdir,Dir}` option. The following shows how the compiler can be called from the Erlang shell:

```
1>asn1ct:compile("People", [ber]).
ok
2>
```

The `verbose` option can be given to have information about the generated files printed:

```

2>asn1ct:compile("People", [ber,verbose]).
Erlang ASN.1 compiling "People.asn"
--{generated,"People.asnldb"}--
--{generated,"People.hrl"}--
--{generated,"People.erl"}--
ok
3>

```

The ASN.1 module `People` is now accepted and the abstract syntax tree is saved in the `People.asnldb` file, the generated Erlang code is compiled using the Erlang compiler and loaded into the Erlang runtime system. Now there is a user interface of `encode/2` and `decode/2` in the module `People`, which is invoked by:

```
'People':encode(<Type name>,<Value>),
```

or

```
'People':decode(<Type name>,<Value>),
```

Alternatively one can use the `asn1rt:encode(<Module name>,<Type name>,<Value>)` and `asn1rt:decode(<Module name>,<Type name>,<Value>)` calls. However, they are not as efficient as the previous methods since they result in an additional `apply/3` call.

Assume there is a network application which receives instances of the ASN.1 defined type `Person`, modifies and sends them back again:

```

receive
  {Port,{data,Bytes}} ->
    case 'People':decode('Person',Bytes) of
      {ok,P} ->
        {ok,Answer} = 'People':encode('Person',mk_answer(P)),
        Port ! {self(),{command,Answer}};
      {error,Reason} ->
        exit({error,Reason})
    end
end,
end,

```

In the example above, a series of bytes is received from an external source and the bytes are then decoded into a valid Erlang term. This was achieved with the call `'People':decode('Person',Bytes)` which returned an Erlang value of the ASN.1 type `Person`. Then an answer was constructed and encoded using `'People':encode('Person',Answer)` which takes an instance of a defined ASN.1 type and transforms it to a binary according to the BER or PER encoding-rules.

The encoder and the decoder can also be run from the shell. The following dialogue with the shell illustrates how the functions `asn1rt:encode/3` and `asn1rt:decode/3` are used.

```

2> Rockstar = {'Person',"Some Name",roving,50}.
{'Person',"Some Name",roving,50}
3> {ok,Bin} = asn1rt:encode('People','Person',Rockstar).
{ok,<<243,17,19,9,83,111,109,101,32,78,97,109,101,2,1,2,
  2,1,50>>}
4> {ok,Person} = asn1rt:decode('People','Person',Bin).
{ok,{'Person',"Some Name",roving,50}}
5>

```

Module dependencies

It is common that `asn1` modules import defined types, values and other entities from another `asn1` module.

Earlier versions of the `asn1` compiler required that modules that were imported from had to be compiled before the module that imported. This caused problems when `asn1` modules had circular dependencies.

Now are referenced modules parsed when the compiler finds an entity that is imported. There will not be any code generated for the referenced module. However, the compiled module rely on that the referenced modules also will be compiled.

1.1.3 The Asn1 Application User Interface

The `Asn1` application provides two separate user interfaces:

- The module `asn1ct` which provides the compile-time functions (including the compiler).
- The module `asn1rt` which provides the run-time functions. However, it is preferable to use the generated `encode/2` and `decode/2` functions in each module, ie. `Module:encode(Type,Value)`, in favor of the `asn1rt` interface.

The reason for the division of the interface into compile-time and run-time is that only run-time modules (`asn1rt*`) need to be loaded in an embedded system.

Compile-time Functions

The ASN.1 compiler can be invoked directly from the command-line by means of the `erlc` program. This is convenient when compiling many ASN.1 files from the command-line or when using Makefiles. Here are some examples of how the `erlc` command can be used to invoke the ASN.1 compiler:

```
erlc Person.asn
erlc -bper Person.asn
erlc -bber ../Example.asn
erlc -o ../asnfiles -I ../asnfiles -I /usr/local/standards/asn1 Person.asn
```

The useful options for the ASN.1 compiler are:

`-b[ber | per | uper]`

Choice of encoding rules, if omitted `ber` is the default.

`-o OutDirectory`

Where to put the generated files, default is the current directory.

`-I IncludeDir`

Where to search for `.asn1db` files and `asn1` source specs in order to resolve references to other modules. This option can be repeated many times if there are several places to search in. The compiler will always search the current directory first.

`+der`

DER encoding rule. Only when using `-ber` option.

`+asn1config`

This functionality works together with the flags `ber`. It enables the specialized decodes, see the *Specialized Decode* chapter.

`+undec_rest`

A buffer that holds a message, being decoded may also have some following bytes. Now it is possible to get those following bytes returned together with the decoded value. If an `asn1` spec is compiled with this option a tuple `{ok, Value, Rest}` is returned. `Rest` may be a list or a binary. Earlier versions of the compiler ignored those following bytes.

+ 'Any Erlc Option'

You may add any option to the Erlang compiler when compiling the generated Erlang files. Any option unrecognised by the `asn1` compiler will be passed to the Erlang compiler.

For a complete description of `erlc` see *Erls Reference Manual*.

The compiler and other compile-time functions can also be invoked from the Erlang shell. Below follows a brief description of the primary functions, for a complete description of each function see *the Asn1 Reference Manual*, the `asn1ct` module.

The compiler is invoked by using `asn1ct:compile/1` with default options, or `asn1ct:compile/2` if explicit options are given. Example:

```
asn1ct:compile("H323-MESSAGES.asn1").
```

which equals:

```
asn1ct:compile("H323-MESSAGES.asn1",[ber]).
```

If one wants PER encoding:

```
asn1ct:compile("H323-MESSAGES.asn1",[per]).
```

The generic encode and decode functions can be invoked like this:

```
asn1ct:encode('H323-MESSAGES','SomeChoiceType',{call,"octetstring"}).  
asn1ct:decode('H323-MESSAGES','SomeChoiceType',Bytes).
```

Or, preferable like:

```
'H323-MESSAGES':encode('SomeChoiceType',{call,"octetstring"}).  
'H323-MESSAGES':decode('SomeChoiceType',Bytes).
```

Run-time Functions

A brief description of the major functions is given here. For a complete description of each function see *the Asn1 Reference Manual*, the `asn1rt` module.

The generic run-time encode and decode functions can be invoked as below:

```
asn1rt:encode('H323-MESSAGES','SomeChoiceType',{call,"octetstring"}).  
asn1rt:decode('H323-MESSAGES','SomeChoiceType',Bytes).
```

Or, preferable like:

```
'H323-MESSAGES':encode('SomeChoiceType',{call,"octetstring"}).
```

1.1 Asn1

```
'H323-MESSAGES':decode('SomeChoiceType',Bytes).
```

The `asn1` nif is enabled in two occasions: encoding of `asn1` values when the `asn1` spec is compiled with `per` and or decode of encoded `asn1` values when the `asn1` spec is compiled with `ber`. In those cases the nif will be loaded automatically at the first call to `encode/decode`. If one doesn't want the performance overhead of the nif being loaded at the first call it is possible to load the nif separately by loading the `asn1rt_nif` module.

By invoking the function `info/0` in a generated module, one gets information about which compiler options were used.

Errors

Errors detected at compile time appear on the screen together with a line number indicating where in the source file the error was detected. If no errors are found, an Erlang ASN.1 module will be created as default.

The run-time encoders and decoders (in the `asn1rt` module) do execute within a catch and returns `{ok, Data}` or `{error, {asn1, Description}}` where `Description` is an Erlang term describing the error.

1.1.4 Multi File Compilation

There are various reasons for using a multi file compilation:

- You want to choose name for the generated module by any reason. Maybe you need to compile the same specs for different encoding/decoding standards.
- You want only one resulting module.

You need to specify which `asn1` specs you will compile in a module that must have the extension `.set.asn`. You chose name of the module and provide the names of the `asn1` specs. For instance, if you have the specs `File1.asn`, `File2.asn` and `File3.asn` your module `MyModule.set.asn` will look like:

```
File1.asn
File2.asn
File3.asn
```

If you compile with:

```
~> erlc MyModule.set.asn
```

the result will be one merged module `MyModule.erl` with the generated code from the three `asn1` specs.

1.1.5 The ASN.1 Types

This section describes the ASN.1 types including their functionality, purpose and how values are assigned in Erlang. ASN.1 has both primitive and constructed types:

<i>Primitive types</i>	<i>Constructed types</i>
<i>BOOLEAN</i>	<i>SEQUENCE</i>
<i>INTEGER</i>	<i>SET</i>
<i>REAL</i>	<i>CHOICE</i>

<i>NULL</i>	<i>SET OF and SEQUENCE OF</i>
<i>ENUMERATED</i>	<i>ANY</i>
<i>BIT STRING</i>	<i>ANY DEFINED BY</i>
<i>OCTET STRING</i>	<i>EXTERNAL</i>
<i>Character Strings</i>	<i>EMBEDDED PDV</i>
<i>OBJECT IDENTIFIER</i>	<i>CHARACTER STRING</i>
<i>Object Descriptor</i>	
<i>The TIME types</i>	

Table 1.1: The supported ASN.1 types

Note:

Values of each ASN.1 type has its own representation in Erlang described in the following subsections. Users shall provide these values for encoding according to the representation, as in the example below.

```
Operational ::= BOOLEAN --ASN.1 definition
```

In Erlang code it may look like:

```
Val = true,
{ok,Bytes}=asn1rt:encode(MyModule,'Operational',Val),
```

Below follows a description of how values of each type can be represented in Erlang.

BOOLEAN

Booleans in ASN.1 express values that can be either TRUE or FALSE. The meanings assigned to TRUE or FALSE is beyond the scope of this text.

In ASN.1 it is possible to have:

```
Operational ::= BOOLEAN
```

Assigning a value to the type Operational in Erlang is possible by using the following Erlang code:

```
Myvar1 = true,
```

1.1 Asn1

Thus, in Erlang the atoms `true` and `false` are used to encode a boolean value.

INTEGER

ASN.1 itself specifies indefinitely large integers, and the Erlang systems with versions 4.3 and higher, support very large integers, in practice indefinitely large integers.

The concept of sub-typing can be applied to integers as well as to other ASN.1 types. The details of sub-typing are not explained here, for further info see []. A variety of syntaxes are allowed when defining a type as an integer:

```
T1 ::= INTEGER
T2 ::= INTEGER (-2..7)
T3 ::= INTEGER (0..MAX)
T4 ::= INTEGER (0<..MAX)
T5 ::= INTEGER (MIN<..-99)
T6 ::= INTEGER {red(0),blue(1),white(2)}
```

The Erlang representation of an ASN.1 INTEGER is an integer or an atom if a so called Named Number List (see T6 above) is specified.

Below is an example of Erlang code which assigns values for the above types:

```
T1value = 0,
T2value = 6,
T6value1 = blue,
T6value2 = 0,
T6value3 = white
```

The Erlang variables above are now bound to valid instances of ASN.1 defined types. This style of value can be passed directly to the encoder for transformation into a series of bytes.

The decoder will return an atom if the value corresponds to a symbol in the Named Number List.

REAL

In this version reals are not implemented. When they are, the following ASN.1 type is used:

```
R1 ::= REAL
```

Can be assigned a value in Erlang as:

```
R1value1 = 2.14,
R1value2 = {256,10,-2},
```

In the last line note that the tuple `{256,10,-2}` is the real number 2.56 in a special notation, which will encode faster than simply stating the number as 2.56. The arity three tuple is `{Mantissa,Base,Exponent}` i.e. `Mantissa * Base^Exponent`.

NULL

Null is suitable in cases where supply and recognition of a value is important but the actual value is not.

```
Notype ::= NULL
```

The NULL type can be assigned in Erlang:

```
N1 = 'NULL',
```

The actual value is the quoted atom 'NULL'.

ENUMERATED

The enumerated type can be used, when the value we wish to describe, may only take one of a set of predefined values.

```
DaysOfTheWeek ::= ENUMERATED {  
    sunday(1),monday(2),tuesday(3),  
    wednesday(4),thursday(5),friday(6),saturday(7) }
```

For example to assign a weekday value in Erlang use the same atom as in the Enumerations of the type definition:

```
Day1 = saturday,
```

The enumerated type is very similar to an integer type, when defined with a set of predefined values. An enumerated type differs from an integer in that it may only have specified values, whereas an integer can also have any other value.

BIT STRING

The BIT STRING type can be used to model information which is made up of arbitrary length series of bits. It is intended to be used for a selection of flags, not for binary files.

In ASN.1 BIT STRING definitions may look like:

```
Bits1 ::= BIT STRING  
Bits2 ::= BIT STRING {foo(0),bar(1),gnu(2),gnome(3),punk(14)}
```

There are five different notations available for representation of BIT STRING values in Erlang and as input to the encode functions.

- A bitstring. By default, a BIT STRING with no symbolic names will be decoded to an Erlang bitstring.
- A list of atoms corresponding to atoms in the NamedBitList in the BIT STRING definition. A BIT STRING with symbolic names will always be decoded to this format.

1.1 Asn1

- A list of binary digits (0 or 1). This format is always accepted as input to the encode functions. A BIT STRING will be decoded to this format if *legacy_bit_string* option has been given. *This format may be withdrawn in a future release.*
- As {Unused, Binary} where Unused denotes how many trailing zero-bits 0 to 7 that are unused in the least significant byte in Binary. This format is always accepted as input to the encode functions. A BIT STRING will be decoded to this format if *compact_bit_string* has been given. *This format may be withdrawn in a future release.*
- A hexadecimal number (or an integer). This format should be avoided, since it is easy to misinterpret a BIT STRING value in this format. *This format may be withdrawn in a future release.*

Note:

It is recommended to either use the bitstring format (for BIT STRINGs with no symbolic names) or a list of symbolic names (for BIT STRINGs with symbolic names). The other formats should be avoided since they may be withdrawn in a future release.

```
Bits1Val1 = <<0:1,1:1,0:1,1:1,1:1>>,
Bits1Val2 = 16#1A,
Bits1Val3 = {3,<<0:1,1:1,0:1,1:1,1:1,0:3>>},
Bits1Val4 = [0,1,0,1,1]
```

Note that Bits1Val1, Bits1Val2, Bits1Val3, and Bits1Val4 denote the same value.

```
Bits2Val1 = [gnu,punk],
Bits2Val2 = <<2#1110:4>>,
Bits2Val3 = [bar,gnu,gnome],
```

Bits2Val2 and Bits2Val3 above denote the same value.

Bits2Val1 is assigned symbolic values. The assignment means that the bits corresponding to gnu and punk i.e. bits 2 and 14 are set to 1 and the rest set to 0. The symbolic values appear as a list of values. If a named value appears, which is not specified in the type definition, a run-time error will occur.

The compact notation equivalent to the empty BIT STRING is {0,<<>>}, which in the other notations is <<>>, [], or 0.

BIT STRINGs may also be sub-typed with, for example, a SIZE specification:

```
Bits3 ::= BIT STRING (SIZE(0..31))
```

This means that no bit higher than 31 can ever be set.

OCTET STRING

The OCTET STRING is the simplest of all ASN.1 types. The OCTET STRING only moves or transfers e.g. binary files or other unstructured information complying to two rules. Firstly, the bytes consist of octets and secondly, encoding is not required.

It is possible to have the following ASN.1 type definitions:

```
01 ::= OCTET STRING
02 ::= OCTET STRING (SIZE(28))
```

With the following example assignments in Erlang:

```
01Val = [17,13,19,20,0,0,255,254],
02Val = "must be exactly 28 chars....",
```

Observe that 01Val is assigned a series of numbers between 0 and 255 i.e. octets. 02Val is assigned using the string notation.

Character Strings

ASN.1 supports a wide variety of character sets. The main difference between OCTET STRINGS and the Character strings is that OCTET STRINGS have no imposed semantics on the bytes delivered.

However, when using for instance the IA5String (which closely resembles ASCII) the byte 65 (in decimal notation) *means* the character 'A'.

For example, if a defined type is to be a VideotexString and an octet is received with the unsigned integer value X, then the octet should be interpreted as specified in the standard ITU-T T.100,T.101.

The ASN.1 to Erlang compiler will not determine the correct interpretation of each BER (Basic Encoding Rules) string octet value with different Character strings. Interpretation of octets is the responsibility of the application. Therefore, from the BER string point of view, octets appear to be very similar to character strings and are compiled in the same way.

It should be noted that when PER (Packed Encoding Rules) is used, there is a significant difference in the encoding scheme between OCTET STRINGS and other strings. The constraints specified for a type are especially important for PER, where they affect the encoding.

Please note that *all* the Character strings are supported and it is possible to use the following ASN.1 type definitions:

```
Digs ::= NumericString (SIZE(1..3))
TextFile ::= IA5String (SIZE(0..64000))
```

and the following Erlang assignments:

```
DigsVal1 = "456",
DigsVal2 = "123",
TextFileVal1 = "abc...xyz...",
TextFileVal2 = [88,76,55,44,99,121 ..... a lot of characters here ....]
```

The Erlang representation for "BMPString" and "UniversalString" is either a list of ASCII values or a list of quadruples. The quadruple representation associates to the Unicode standard representation of characters. The ASCII characters are all represented by quadruples beginning with three zeros like {0,0,0,65} for the 'A' character. When decoding a value for these strings the result is a list of quadruples, or integers when the value is an ASCII character. The following example shows how it works:

In a file PrimStrings.asn1 the type BMP is defined as

1.1 Asn1

BMP ::= BMPString then using BER encoding (ber option) the input/output format will be:

```
1> {ok,Bytes1} = asn1rt:encode('PrimStrings','BMP',[{0,0,53,53},{0,0,45,56}]).
{ok,[30,4,"55-8"]}
2> asn1rt:decode('PrimStrings','BMP',list_to_binary(Bytes1)).
{ok,[{0,0,53,53},{0,0,45,56}]}
3> {ok,Bytes2} = asn1rt:encode('PrimStrings','BMP',[{0,0,53,53},{0,0,0,65}]).
{ok,[30,4,[53,53,0,65]]}
4> asn1rt:decode('PrimStrings','BMP',list_to_binary(Bytes2)).
{ok,[{0,0,53,53},65]}
5> {ok,Bytes3} = asn1rt:encode('PrimStrings','BMP',"BMP string").
{ok,[30,20,[0,66,0,77,0,80,0,32,0,115,0,116,0,114,0,105,0,110,0,103]]}
6> asn1rt:decode('PrimStrings','BMP',list_to_binary(Bytes3)).
{ok,"BMP string"}
```

The UTF8String is represented in Erlang as a list of integers, where each integer represents the unicode value of one character. When a value shall be encoded one first has to transform it to a UTF8 encoded binary, then it can be encoded by asn1. When decoding the result is a UTF8 encoded binary, which may be transformed to an integer list. The transformation functions, `utf8_binary_to_list` and `utf8_list_to_binary`, are in the `asn1rt` module. In the example below we assume an `asn1` definition `UTF ::= UTF8String` in a module `UTF.asn`:

```
1> asn1ct:compile('UTF',[ber]).
Erlang ASN.1 version "1.4.3.3" compiling "UTF.asn"
Compiler Options: [ber]
--{generated,"UTF.asnldb"}--
--{generated,"UTF.erl"}--
ok
2> UTF8Val1 = "hello".
"hello"
3> {ok,UTF8bin1} = asn1rt:utf8_list_to_binary(UTF8Val1).
{ok,<<104,101,108,108,111>>}
4> {ok,B} = 'UTF':encode('UTF',UTF8bin1).
{ok,[12,
    5,
    <<104,101,108,108,111>>]}
5> Bin = list_to_binary(B).
<<12,5,104,101,108,108,111>>
6> {ok,UTF8bin1} = 'UTF':decode('UTF',Bin).
{ok,<<104,101,108,108,111>>}
7> asn1rt:utf8_binary_to_list(UTF8bin1).
{ok,"hello"}
8> UTF8Val2 = [16#00,16#100,16#ffff,16#ffffff].
[0,256,65535,16777215]
9> {ok,UTF8bin2} = asn1rt:utf8_list_to_binary(UTF8Val2).
{ok,<<0,196,128,239,191,191,248,191,191,191,191>>}
10> {ok,B2} = 'UTF':encode('UTF',UTF8bin2).
{ok,[12,
    11,
    <<0,196,128,239,191,191,248,191,191,191,191>>]}
11> Bin2 = list_to_binary(B2).
<<12,11,0,196,128,239,191,191,248,191,191,191,191>>
12> {ok,UTF8bin2} = 'UTF':decode('UTF',Bin2).
{ok,<<0,196,128,239,191,191,248,191,191,191,191>>}
13> asn1rt:utf8_binary_to_list(UTF8bin2).
{ok,[0,256,65535,16777215]}
14>
```

OBJECT IDENTIFIER

The OBJECT IDENTIFIER is used whenever a unique identity is required. An ASN.1 module, a transfer syntax, etc. is identified with an OBJECT IDENTIFIER. Assume the example below:

```
Oid ::= OBJECT IDENTIFIER
```

Therefore, the example below is a valid Erlang instance of the type 'Oid'.

```
OidVal1 = {1,2,55},
```

The OBJECT IDENTIFIER value is simply a tuple with the consecutive values which must be integers.

The first value is limited to the values 0, 1 or 2 and the second value must be in the range 0..39 when the first value is 0 or 1.

The OBJECT IDENTIFIER is a very important type and it is widely used within different standards to uniquely identify various objects. In [], there is an easy-to-understand description of the usage of OBJECT IDENTIFIER.

Object Descriptor

Values of this type can be assigned a value as an ordinary string i.e.

"This is the value of an Object descriptor"

The TIME Types

Two different time types are defined within ASN.1, Generalized Time and UTC (Universal Time Coordinated), both are assigned a value as an ordinary string within double quotes i.e. "19820102070533.8".

In case of DER encoding the compiler does not check the validity of the time values. The DER requirements upon those strings is regarded as a matter for the application to fulfill.

SEQUENCE

The structured types of ASN.1 are constructed from other types in a manner similar to the concepts of array and struct in C.

A SEQUENCE in ASN.1 is comparable with a struct in C and a record in Erlang. A SEQUENCE may be defined as:

```
Pdu ::= SEQUENCE {  
    a INTEGER,  
    b REAL,  
    c OBJECT IDENTIFIER,  
    d NULL }
```

This is a 4-component structure called 'Pdu'. The major format for representation of SEQUENCE in Erlang is the record format. For each SEQUENCE and SET in an ASN.1 module an Erlang record declaration is generated. For Pdu above, a record like this is defined:

```
-record('Pdu',{a, b, c, d}).
```

1.1 Asn1

The record declarations for a module M are placed in a separate M.hrl file.

Values can be assigned in Erlang as shown below:

```
MyPdu = #'Pdu'{a=22,b=77.99,c={0,1,2,3,4},d='NULL'}.
```

The decode functions will return a record as result when decoding a SEQUENCE or a SET.

A SEQUENCE and a SET may contain a component with a DEFAULT key word followed by the actual value that is the default value. In case of BER encoding it is optional to encode the value if it equals the default value. If the application uses the atom asn1_DEFAULT as value or if the value is a primitive value that equals the default value the encoding omits the bytes for this value, which is more efficient and it results in fewer bytes to send to the receiving application.

For instance, if the following types exists in a file "File.asn":

```
Seq1 ::= SEQUENCE {
    a INTEGER DEFAULT 1,
    b Seq2 DEFAULT {aa TRUE, bb 15}
}

Seq2 ::= SEQUENCE {
    aa BOOLEAN,
    bb INTEGER
}
```

Some values and the corresponding encoding in an Erlang terminal is shown below:

```
1> asn1ct:compile('File').
Erlang ASN.1 version "1.3.2" compiling "File.asn1"
Compiler Options: []
--{generated,"File.asnldb"}--
--{generated,"File.hrl"}--
--{generated,"File.erl"}--
ok
2> 'File':encode('Seq1',{ 'Seq1',asn1_DEFAULT,asn1_DEFAULT}).
{ok,["0",[0],[[]],[[]]]}
3> lists:flatten(["0",[0],[[]],[[]]]).
[48,0]
4> 'File':encode('Seq1',{ 'Seq1',1,{ 'Seq2',true,15}}).
{ok,["0","\b",[[]],["\241",[6],[[128],[1],"\377",[129],[1],[15]]]]]}
5> lists:flatten(["0","\b",[[]],["\241",[6],[[128],[1],"\377",[129],[1],[15]]]]).
[48,8,161,6,128,1,255,129,1,15]
6>
```

The result after command line 3, in the example above, shows that the encoder omits the encoding of default values when they are specific by asn1_DEFAULT. Line 5 shows that even primitive values that equals the default value are detected and not encoded. But the constructed value of component b in Seq1 is not recognized as the default value. Checking of default values in BER is not done in case of complex values, because it would be too expensive.

But, the DER encoding format has stronger requirements regarding default values both for SET and SEQUENCE. A more elaborate and time expensive check of default values will take place. The following is an example with the same types and values as above but with der encoding format.

```

1> asn1ct:compile('File',[der]).
Erlang ASN.1 version "1.3.2" compiling "File.asn1"
Compiler Options: [der]
--{generated,"File.asn1db"}--
--{generated,"File.hrl"}--
--{generated,"File.erl"}--
ok
2> 'File':encode('Seq1',{'Seq1',asn1_DEFAULT,asn1_DEFAULT}).
{ok,["0",[0],[[]],[[]]]}
3> lists:flatten(["0",[0],[[]],[[]]]).
[48,0]
4> 'File':encode('Seq1',{'Seq1',1,'Seq2',true,15}).
{ok,["0",[0],[[]],[[]]]}
5> lists:flatten(["0",[0],[[]],[[]]]).
[48,0]
6>

```

Line 5 shows that even values of constructed types is checked and if it equals the default value it will not be encoded.

SET

The SET type is an unusual construct and normally the SEQUENCE type is more appropriate to use. Set is also inefficient compared with SEQUENCE, as the components can be in any order. Hence, it must be possible to distinguish every component in 'SET', both when encoding and decoding a value of a type defined to be a SET. The tags of all components must be different from each other in order to be easily recognizable.

A SET may be defined as:

```

Pdu2 ::= SET {
  a INTEGER,
  b BOOLEAN,
  c ENUMERATED {on(0),off(1)} }

```

A SET is represented as an Erlang record. For each SEQUENCE and SET in an ASN.1 module an Erlang record declaration is generated. For Pdu2 above a record is defined like this:

```

-record('Pdu2',{a, b, c}).

```

The record declarations for a module M are placed in a separate M.hrl file.

Values can be assigned in Erlang as demonstrated below:

```

V = #'Pdu2'{a=44,b=false,c=off}.

```

The decode functions will return a record as result when decoding a SET.

The difference between SET and SEQUENCE is that the order of the components (in the BER encoded format) is undefined for SET and defined as the lexical order from the ASN.1 definition for SEQUENCE. The ASN.1 compiler for Erlang will always encode a SET in the lexical order. The decode routines can handle SET components encoded in any order but will always return the result as a record. Since all components of the SET must be distinguishable both in the encoding phase as well as the decoding phase the following type is not allowed in a module with EXPLICIT or IMPLICIT as tag-default :

1.1 Asn1

```
Bad ::= SET {i INTEGER,
             j INTEGER }
```

The ASN.1 to Erlang compiler rejects the above type. We shall not explain the concept of tag further here, we refer to [].

Encoding of a SET with components with DEFAULT values behaves similar as a SEQUENCE, *see above*. The DER encoding format restrictions on DEFAULT values is the same for SET as for SEQUENCE, and is supported by the compiler, *see above*.

Moreover, in DER the elements of a SET will be sorted. If a component is an un-tagged choice the sorting have to take place in run-time. This fact emphasizes the following recommendation if DER encoding format is used.

The concept of SET is an unusual construct and one cannot think of one single application where the set type is essential. (Imagine if someone "invented" the shuffled array in 'C') People tend to think that 'SET' sounds nicer and more mathematical than 'SEQUENCE' and hence use it when 'SEQUENCE' would have been more appropriate. It is also most inefficient, since every correct implementation of SET must always be prepared to accept the components in any order. So, if possible use SEQUENCE instead of SET.

Notes about Extend-ability for SEQUENCE and SET

When a SEQUENCE or SET contains an extension marker and extension components like this:

```
SExt ::= SEQUENCE {
        a INTEGER,
        ...,
        b BOOLEAN }
```

It means that the type may get more components in newer versions of the ASN.1 spec. In this case it has got a new component b. Thus, incoming messages that will be decoded may have more or fewer components than this one.

The component b will be treated as an original component when encoding a message. In this case, as it is not an optional element, it must be encoded.

During decoding the b field of the record will get the decoded value of the b component if present and otherwise the value `asn1_NOVALUE`.

CHOICE

The CHOICE type is a space saver and is similar to the concept of a 'union' in the C-language. As with the previous SET-type, the tags of all components of a CHOICE need to be distinct. If AUTOMATIC TAGS are defined for the module (which is preferable) the tags can be omitted completely in the ASN.1 specification of a CHOICE.

Assume:

```
T ::= CHOICE {
    x [0] REAL,
    y [1] INTEGER,
    z [2] OBJECT IDENTIFIER }
```

It is then possible to assign values:

```
TVal1 = {y,17},
TVal2 = {z,{0,1,2}},
```

A CHOICE value is always represented as the tuple {ChoiceAlternative, Val} where ChoiceAlternative is an atom denoting the selected choice alternative.

It is also allowed to have a CHOICE type tagged as follow:

```
C ::= [PRIVATE 111] CHOICE {
    C1,
    C2 }

C1 ::= CHOICE {
    a [0] INTEGER,
    b [1] BOOLEAN }

C2 ::= CHOICE {
    c [2] INTEGER,
    d [3] OCTET STRING }
```

In this case, the top type C appears to have no tags at all in its components, however, both C1 and C2 are also defined as CHOICE types and they have distinct tags among themselves. Hence, the above type C is both legal and allowed.

Extendable CHOICE

When a CHOICE contains an extension marker and the decoder detects an unknown alternative of the CHOICE the value is represented as:

```
{asn1_ExtAlt, BytesForOpenType}
```

Where BytesForOpenType is a list of bytes constituting the encoding of the "unknown" CHOICE alternative.

SET OF and SEQUENCE OF

The SET OF and SEQUENCE OF types correspond to the concept of an array found in several programming languages. The Erlang syntax for both of these types is straight forward. For example:

```
Arr1 ::= SET SIZE (5) OF INTEGER (4..9)
Arr2 ::= SEQUENCE OF OCTET STRING
```

We may have the following in Erlang:

```
Arr1Val = [4,5,6,7,8],
Arr2Val = ["abc", [14,34,54], "Octets"],
```

Please note that the definition of the SET OF type implies that the order of the components is undefined, but in practice there is no difference between SET OF and SEQUENCE OF. The ASN.1 compiler for Erlang does not randomize the order of the SET OF components before encoding.

However, in case of a value of the type SET OF, the DER encoding format requires the elements to be sent in ascending order of their encoding, which implies an expensive sorting procedure in run-time. Therefore it is strongly recommended to use SEQUENCE OF instead of SET OF if it is possible.

ANY and ANY DEFINED BY

The types `ANY` and `ANY DEFINED BY` have been removed from the standard since 1994. It is recommended not to use these types any more. They may, however, exist in some old ASN.1 modules. The idea with this type was to leave a "hole" in a definition where one could put unspecified data of any kind, even non ASN.1 data.

A value of this type is encoded as an open type.

Instead of `ANY/ANY DEFINED BY` one should use `information object class`, `table constraints` and `parameterization`. In particular the construct `TYPE-IDENTIFIER.@Type` accomplish the same as the deprecated `ANY`.

See also *Information object*

EXTERNAL, EMBEDDED PDV and CHARACTER STRING

These types are used in presentation layer negotiation. They are encoded according to their associated type, see [].

The `EXTERNAL` type had a slightly different associated type before 1994. [] states that encoding shall follow the older associated type. Therefore does generated encode/decode functions convert values of the newer format to the older format before encoding. This implies that it is allowed to use `EXTERNAL` type values of either format for encoding. Decoded values are always returned on the newer format.

Embedded Named Types

The structured types previously described may very well have other named types as their components. The general syntax to assign a value to the component `C` of a named ASN.1 type `T` in Erlang is the record syntax `#'T'{'C'=Value}`. Where `Value` may be a value of yet another type `T2`.

For example:

```
B ::= SEQUENCE {
    a Arr1,
    b [0] T }

Arr1 ::= SET SIZE (5) OF INTEGER (4..9)

T ::= CHOICE {
    x [0] REAL,
    y [1] INTEGER,
    z [2] OBJECT IDENTIFIER }
```

The above example can be assigned like this in Erlang:

```
V2 = #'B'{a=[4,5,6,7,8], b={x,7.77}}.
```

1.1.6 Naming of Records in .hrl Files

When an `asn1` specification is compiled all defined types of type `SET` or `SEQUENCE` will result in a corresponding record in the generated `hrl` file. This is because the values for `SET/SEQUENCE` as mentioned in sections above are represented as records.

Though there are some special cases of this functionality that are presented below.

Embedded Structured Types

It is also possible in ASN.1 to have components that are themselves structured types. For example, it is possible to have:

```

Emb ::= SEQUENCE {
  a SEQUENCE OF OCTET STRING,
  b SET {
    a [0] INTEGER,
    b [1] INTEGER DEFAULT 66},
  c CHOICE {
    a INTEGER,
    b FooType } }

FooType ::= [3] VisibleString

```

The following records are generated because of the type Emb:

```

-record('Emb',{a, b, c}).
-record('Emb_b',{a, b = asn1_DEFAULT}). % the embedded SET type

```

Values of the Emb type can be assigned like this:

```

V = #'Emb'{a=["qqqq",[1,2,255]],
           b = #'Emb_b'{a=99},
           c ={b,"Can you see this"}}.

```

For an embedded type of type SEQUENCE/SET in a SEQUENCE/SET the record name is extended with an underscore and the component name. If the embedded structure is deeper with SEQUENCE, SET or CHOICE types in the line, each component-/alternative-name will be added to the record-name.

For example:

```

Seq ::= SEQUENCE{
  a CHOICE{
    b SEQUENCE {
      c INTEGER
    }
  }
}

```

will result in the following record:

```

-record('Seq_a_b',{c}).

```

If the structured type has a component with an embedded SEQUENCE OF/SET OF which embedded type in turn is a SEQUENCE/SET it will give a record with the SEQOF/SETOF addition as in the following example:

```

Seq ::= SEQUENCE {
  a SEQUENCE OF SEQUENCE {
    b
  }
  c SET OF SEQUENCE {
    d
  }
}

```

1.1 Asn1

```
    }  
}
```

This results in the records:

```
-record('Seq_a_SEQOF'{b}).  
-record('Seq_c_SETOF'{d}).
```

A parameterized type should be considered as an embedded type. Each time a such type is referenced an instance of it is defined. Thus in the following example a record with name 'Seq_b' is generated in the .hrl file and used to hold values.

```
Seq ::= SEQUENCE {  
    b PType{INTEGER}  
}  
  
PType{T} ::= SEQUENCE{  
    id T  
}
```

Recursive Types

Types may refer to themselves. Suppose:

```
Rec ::= CHOICE {  
    nothing [0] NULL,  
    something SEQUENCE {  
        a INTEGER,  
        b OCTET STRING,  
        c Rec }}  

```

This type is recursive; that is, it refers to itself. This is allowed in ASN.1 and the ASN.1-to-Erlang compiler supports this recursive type. A value for this type is assigned in Erlang as shown below:

```
V = {something, #'Rec_something'{a = 77,  
                                b = "some octets here",  
                                c = {nothing, 'NULL'}}}.
```

1.1.7 ASN.1 Values

Values can be assigned to ASN.1 type within the ASN.1 code itself, as opposed to the actions taken in the previous chapter where a value was assigned to an ASN.1 type in Erlang. The full value syntax of ASN.1 is supported and [X.680] describes in detail how to assign values in ASN.1. Below is a short example:

```
TT ::= SEQUENCE {  
    a INTEGER,  
    b SET OF OCTET STRING }  
  
tt TT ::= {a 77, b {"kalle", "ku!a"}}
```

The value defined here could be used in several ways. Firstly, it could be used as the value in some DEFAULT component:

```
SS ::= SET {
    s [0] OBJECT IDENTIFIER,
    val TT DEFAULT tt }
```

It could also be used from inside an Erlang program. If the above ASN.1 code was defined in ASN.1 module `Values`, then the ASN.1 value `tt` can be reached from Erlang as a function call to `'Values':tt()` as in the example below.

```
1> Val = 'Values':tt().
{'TT',77,['kalle',"kula"]}
2> {ok,Bytes} = 'Values':encode('TT',Val).
{ok,<<48,18,128,1,77,161,13,4,5,107,97,108,108,101,4,4,
    107,117,108,97>>}
4> 'Values':decode('TT',Bytes).
{ok,{'TT',77,['kalle',"kula"]}}
```

The above example shows that a function is generated by the compiler that returns a valid Erlang representation of the value, even though the value is of a complex type.

Furthermore, there is a macro generated for each value in the .hrl file. So, the defined value `tt` can also be extracted by `?tt` in application code.

1.1.8 Macros

MACRO is not supported as the the type is no longer part of the ASN.1 standard.

1.1.9 ASN.1 Information Objects (X.681)

Information Object Classes, Information Objects and Information Object Sets, (in the following called classes, objects and object sets respectively), are defined in the standard definition []. In the following only a brief explanation is given.

These constructs makes it possible to define open types, i.e. values of that type can be of any ASN.1 type. It is also possible to define relationships between different types and values, since classes can hold types, values, objects, object sets and other classes in its fields. An Information Object Class may be defined in ASN.1 as:

```
GENERAL-PROCEDURE ::= CLASS {
    &Message,
    &Reply          OPTIONAL,
    &Error          OPTIONAL,
    &id             PrintableString UNIQUE
}
WITH SYNTAX {
    NEW MESSAGE    &Message
    [REPLY        &Reply]
    [ERROR        &Error]
    ADDRESS       &id
}
```

An object is an instance of a class and an object set is a set containing objects of one specified class. A definition may look like below.

1.1 Asn1

The object `object1` is an instance of the CLASS GENERAL-PROCEDURE and has one type field and one fixed type value field. The object `object2` also has an OPTIONAL field `ERROR`, which is a type field.

```
object1 GENERAL-PROCEDURE ::= {  
  NEW MESSAGE      PrintableString  
  ADDRESS          "home"  
}  
  
object2 GENERAL-PROCEDURE ::= {  
  NEW MESSAGE INTEGER  
  ERROR INTEGER  
  ADDRESS "remote"  
}
```

The field `ADDRESS` is a UNIQUE field. Objects in an object set must have unique values in their UNIQUE field, as in GENERAL-PROCEDURES:

```
GENERAL-PROCEDURES GENERAL-PROCEDURE ::= {  
  object1 | object2}
```

One can not encode a class, object or object set, only referring to it when defining other ASN.1 entities. Typically one refers to a class and to object sets by table constraints and component relation constraints [] in ASN.1 types, as in:

```
StartMessage ::= SEQUENCE {  
  msgId GENERAL-PROCEDURE.&id ({GENERAL-PROCEDURES}),  
  content GENERAL-PROCEDURE.&Message ({GENERAL-PROCEDURES}@msgId),  
}
```

In the type `StartMessage` the constraint following the `content` field tells that in a value of type `StartMessage` the value in the `content` field must come from the same object that is chosen by the `msgId` field.

So, the value `#'StartMessage' {msgId="home", content="Any Printable String"}` is legal to encode as a `StartMessage` value, while the value `#'StartMessage' {msgId="remote", content="Some String"}` is illegal since the constraint in `StartMessage` tells that when you have chosen a value from a specific object in the object set `GENERAL-PROCEDURES` in the `msgId` field you have to choose a value from that same object in the `content` field too. In this second case it should have been any `INTEGER` value.

`StartMessage` can in the `content` field be encoded with a value of any type that an object in the `GENERAL-PROCEDURES` object set has in its `NEW MESSAGE` field. This field refers to a type field `&Message` in the class. The `msgId` field is always encoded as a `PrintableString`, since the field refers to a fixed type in the class.

1.1.10 Parameterization (X.683)

Parameterization, which is defined in the standard [], can be used when defining types, values, value sets, information object classes, information objects or information object sets. A part of a definition can be supplied as a parameter. For instance, if a Type is used in a definition with certain purpose, one want the type-name to express the intention. This can be done with parameterization.

When many types (or an other ASN.1 entity) only differs in some minor cases, but the structure of the types are similar, only one general type can be defined and the differences may be supplied through parameters.

One example of use of parameterization is:

```

General{Type} ::= SEQUENCE
{
    number    INTEGER,
    string    Type
}

T1 ::= General{PrintableString}
T2 ::= General{BIT STRING}

```

An example of a value that can be encoded as type T1 is {12,"hello"}.

Observe that the compiler not generates encode/decode functions for parameterized types, only for the instances of the parameterized types. So, if a file contains the types General{ }, T1 and T2 above, encode/decode functions will only be generated for T1 and T2.

1.1.11 Tags

Every built-in ASN.1 type, except CHOICE and ANY have a universal tag. This is a unique number that clearly identifies the type.

It is essential for all users of ASN.1 to understand all the details about tags.

Tags are implicitly encoded in the BER encoding as shown below, but are hardly not accounted for in the PER encoding. In PER tags are used for instance to sort the components of a SET.

There are four different types of tags.

universal

For types whose meaning is the same in all applications. Such as integers, sequences and so on; that is, all the built in types.

application

For application specific types for example, the types in X.400 Message handling service have this sort of tag.

private

For your own private types.

context

This is used to distinguish otherwise indistinguishable types in a specific context. For example, if we have two components of a CHOICE type that are both INTEGER values, there is no way for the decoder to decipher which component was actually chosen, since both components will be tagged as INTEGER. When this or similar situations occur, one or both of the components should be given a context specific to resolve the ambiguity.

The tag in the case of the 'Apdu' type [PRIVATE 1] is encoded to a sequence of bytes making it possible for a decoder to look at the (initial) bytes that arrive and determine whether the rest of the bytes must be of the type associated with that particular sequence of bytes. This means that each tag must be uniquely associated with *only* one ASN.1 type.

Immediately following the tag is a sequence of bytes informing the decoder of the length of the instance. This is sometimes referred to as TLV (Tag length value) encoding. Hence, the structure of a BER encoded series of bytes is as shown in the table below.

Tag	Len	Value
-----	-----	-------

Table 1.2: Structure of a BER encoded series of bytes

1.1.12 Encoding Rules

When the first recommendation on ASN.1 was released 1988 it was accompanied with the Basic Encoding Rules, BER, as the only alternative for encoding. BER is a somewhat verbose protocol. It adopts a so-called TLV (type, length, value) approach to encoding in which every element of the encoding carries some type information, some length information and then the value of that element. Where the element is itself structured, then the Value part of the element is itself a series of embedded TLV components, to whatever depth is necessary. In summary, BER is not a compact encoding but is relatively fast and easy to produce.

The DER (Distinguished Encoding Rule) encoding format was included in the standard in 1994. It is a specialized form of BER, which gives the encoder the option to encode some entities differently. For instance, is the value for TRUE any octet with any bit set to one. But, DER does not leave any such choices. The value for TRUE in the DER case is encoded as the octet 11111111. So, the same value encoded by two different DER encoders must result in the same bit stream.

A more compact encoding is achieved with the Packed Encoding Rules PER which was introduced together with the revised recommendation in 1994. PER takes a rather different approach from that taken by BER. The first difference is that the tag part in the TLV is omitted from the encodings, and any tags in the notation are not encoded. The potential ambiguities are resolved as follows:

- A CHOICE is encoded by first encoding a choice index which identifies the chosen alternative by its position in the notation.
- The elements of a SEQUENCE are transmitted in textual order. OPTIONAL or DEFAULT elements are preceded by a bit map to identify which elements are present. After sorting the elements of a SET in the "canonical tag order" as defined in X.680 8.6 they are treated as a SEQUENCE regarding OPTIONAL and DEFAULT elements. A SET is transferred in the sorted order.

A second difference is that PER takes full account of the sub-typing information in that the encoded bytes are affected by the constraints. The BER encoded bytes are unaffected by the constraints. PER uses the sub-typing information to for example omit length fields whenever possible.

The run-time functions, sometimes take the constraints into account both for BER and PER. For instance are SIZE constrained strings checked.

There are two variants of PER, *aligned* and *unaligned*. In summary, PER results in compact encodings which require much more computation to produce than BER.

1.2 Specialized Decodes

When performance is of highest priority and one is interested in a limited part of the ASN.1 encoded message, before one decide what to do with the rest of it, one may want to decode only this small part. The situation may be a server that has to decide to which addressee it will send a message. The addressee may be interested in the entire message, but the server may be a bottleneck that one want to spare any unnecessary load. Instead of making two *complete decodes* (the normal case of decode), one in the server and one in the addressee, it is only necessary to make one *specialized decode* (in the server) and another complete decode (in the addressee). The following specialized decodes *exclusive decode* and *selected decode* support to solve this and similar problems.

So far this functionality is only provided when using the optimized BER_BIN version, that is when compiling with the options `ber_bin` and `optimize`. It does also work using the `nif` option. We have no intent to make this available on the default BER version, but maybe in the PER_BIN version (`per_bin`).

1.2.1 Exclusive Decode

The basic idea with exclusive decode is that you specify which parts of the message you want to exclude from being decoded. These parts remain encoded and are returned in the value structure as binaries. They may be decoded in turn by passing them to a certain `decode_part/2` function. The performance gain is high when the message is large

and you can do an exclusive decode and later on one or several decodes of the parts or a second complete decode instead of two or more complete decodes.

How To Make It Work

In order to make exclusive decode work you have to do the following:

- First, decide the name of the function for the exclusive decode.
- Second, write instructions that must consist of the name of the exclusive decode function, the name of the ASN.1 specification and a notation that tells which parts of the message structure will be excluded from decode. These instructions shall be included in a configuration file.
- Third, compile with the additional option `asn1config`. The compiler searches for a configuration file with the same name as the ASN.1 spec but with the extension `.asn1config`. This configuration file is not the same as used for compilation of a set of files. See section *Writing an Exclusive Decode Instruction*.

User Interface

The run-time user interface for exclusive decode consists of two different functions. First, the function for an exclusive decode, whose name the user decides in the configuration file. Second, the compiler generates a `decode_part/2` function when exclusive decode is chosen. This function decodes the parts that were left undecoded during the exclusive decode. Both functions are described below.

If the exclusive decode function has for example got the name `decode_exclusive` and an ASN.1 encoded message `Bin` shall be exclusive decoded, the call is:

```
{ok,Excl_Message} = 'MyModule':decode_exclusive(Bin)
```

The result `Excl_Message` has the same structure as an complete decode would have, except for the parts of the top-type that were not decoded. The undecoded parts will be on their place in the structure on the format `{Type_Key, Undecoded_Value}`.

Each undecoded part that shall be decoded must be fed into the `decode_part/2` function, like:

```
{ok,Part_Message} = 'MyModule':decode_part(Type_Key,Undecoded_Value)
```

Writing an Exclusive Decode Instruction

This instruction is written in the configuration file on the format:

```
Exclusive_Decode_Instruction = {exclusive_decode,{Module_Name,Decode_Instructions}}.  
Module_Name = atom()  
Decode_Instructions = [Decode_Instruction]+  
Decode_Instruction = {Exclusive_Decode_Function_Name,Type_List}  
Exclusive_Decode_Function_Name = atom()  
Type_List = [Top_Type,Element_List]  
Element_List = [Element]+  
Element = {Name,parts} |
```

1.2 Specialized Decodes

```
        {Name,undecoded} |
        {Name,Element_List}

Top_Type = atom()

Name = atom()
```

Observe that the instruction must be a valid Erlang term ended by a dot.

In the `Type_List` the "path" from the top type to each undecoded sub-components is described. The top type of the path is an atom, the name of it. The action on each component/type that follows will be described by one of `{Name,parts}`, `{Name,undecoded}`, `{Name,Element_List}`

The use and effect of the actions are:

- `{Name,undecoded}` Tells that the element will be left undecoded during the exclusive decode. The type of `Name` may be any ASN.1 type. The value of element `Name` will be returned as a tuple, as mentioned *above*, in the value structure of the top type.
- `{Name,parts}` The type of `Name` may be one of SEQUENCE OF or SET OF. The action implies that the different components of `Name` will be left undecoded. The value of `Name` will be returned as a tuple, as *above*, where the second element is a list of binaries. That is because the representation of a SEQUENCE OF/ SET OF in Erlang is a list of its internal type. Any of the elements of this list or the entire list can be decoded by the `decode_part` function.
- `{Name,Element_List}` This action is used when one or more of the sub-types of `Name` will be exclusive decoded.

`Name` in the actions above may be a component name of a SEQUENCE or a SET or a name of an alternative in a CHOICE.

Example

In the examples below we use the definitions from the following ASN.1 spec:

```
GUI DEFINITIONS AUTOMATIC TAGS ::=
BEGIN

Action ::= SEQUENCE
{
    number  INTEGER DEFAULT 15,
    handle  [0] Handle DEFAULT {number 12, on  TRUE}
}

Key ::= [11] EXPLICIT Button
Handle ::= [12] Key
Button ::= SEQUENCE
{
    number  INTEGER,
    on      BOOLEAN
}

Window ::= CHOICE
{
    vsn INTEGER,
    status E
}

Status ::= SEQUENCE
```

```

{
  state INTEGER,
  buttonList SEQUENCE OF Button,
  enabled BOOLEAN OPTIONAL,
  actions CHOICE {
    possibleActions SEQUENCE OF Action,
    noOfActions INTEGER
  }
}

END

```

If Button is a top type and we want to exclude component number from decode the Type_List in the instruction in the configuration file will be ['Button', [{number,undecoded}]]. If we call the decode function decode_Button_exclusive the Decode_Instruction will be {decode_Button_exclusive, ['Button', [{number,undecoded}]]}.

We also have another top type Window whose sub component actions in type Status and the parts of component buttonList shall be left undecoded. For this type we name the function decode__Window_exclusive. The whole Exclusive_Decode_Instruction configuration is as follows:

```

{exclusive_decode,{ 'GUI',
  [{decode_Window_exclusive,['Window',[{status,[{buttonList,parts},{actions,undecoded}}]}],
   {decode_Button_exclusive,['Button',[{number,undecoded}]]}]}].

```

Figure 2.1: Figure symbolizes the bytes of a Window:status message. The components buttonList and actions are excluded from decode. Only state and enabled are decoded when decode__Window_exclusive is called.

Compiling GUI.asn including the configuration file is done like:

```

unix> erlc -bber_bin +optimize +asn1config GUI.asn
erlang> asn1ct:compile('GUI',[ber_bin,optimize,asn1config]).

```

The module can be used like:

```

1> Button_Msg = {'Button',123,true}.
{'Button',123,true}
2> {ok,Button_Bytes} = 'GUI':encode('Button',Button_Msg).
{ok,[<<48>>,
    [6],
    [<<128>>,
    [1],
    123],
    [<<129>>,
    [1],
    255]]}
3> {ok,Exclusive_Msg_Button} = 'GUI':decode_Button_exclusive(list_to_binary(Button_Bytes)).
{ok,{'Button',{'Button_number',<<28,1,123>>},
    true}}

```

1.2 Specialized Decodes

```
4> 'GUI':decode_part('Button_number',<<128,1,123>>).
{ok,123}
5> Window_Msg =
{'Window',{status,{ 'Status',35,
    [{ 'Button',3,true},
     { 'Button',4,false},
     { 'Button',5,true},
     { 'Button',6,true},
     { 'Button',7,false},
     { 'Button',8,true},
     { 'Button',9,true},
     { 'Button',10,false},
     { 'Button',11,true},
     { 'Button',12,true},
     { 'Button',13,false},
     { 'Button',14,true}],
    false,
    {possibleActions,[{ 'Action',16,{ 'Button',17,true}}]}}}},
{'Window',{status,{ 'Status',35,
    [{ 'Button',3,true},
     { 'Button',4,false},
     { 'Button',5,true},
     { 'Button',6,true},
     { 'Button',7,false},
     { 'Button',8,true},
     { 'Button',9,true},
     { 'Button',10,false},
     { 'Button',11,true},
     { 'Button',12,true},
     { 'Button',13,false},
     { 'Button',14,true}],
    false,
    {possibleActions,[{ 'Action',16,{ 'Button',17,true}}]}}}}}
6> {ok,Window_Bytes}='GUI':encode('Window',Window_Msg).
{ok,[<<161>>,
    [127],
    [<<128>>, ...

8> {ok,{status,{ 'Status',Int,{Type_Key_Seq0f,Val_SEQ0F},
BoolOpt,{Type_Key_Choice,Val_Choice}}}}=
'GUI':decode_Window_status_exclusive(list_to_binary(Window_Bytes)).
{ok,{status,{ 'Status',35,
    { 'Status_buttonList',[<<48,6,128,1,3,129,1,255>>,
        <<48,6,128,1,4,129,1,0>>,
        <<48,6,128,1,5,129,1,255>>,
        <<48,6,128,1,6,129,1,255>>,
        <<48,6,128,1,7,129,1,0>>,
        <<48,6,128,1,8,129,1,255>>,
        <<48,6,128,1,9,129,1,255>>,
        <<48,6,128,1,10,129,1,0>>,
        <<48,6,128,1,11,129,1,255>>,
        <<48,6,128,1,12,129,1,255>>,
        <<48,6,128,1,13,129,1,0>>,
        <<48,6,128,1,14,129,1,255>>]},
    false,
    { 'Status_actions',
<<163,21,160,19,48,17,2,1,16,160,12,172,10,171,8,48,6,128,1,...>>}}}}
10> 'GUI':decode_part(Type_Key_Seq0f,Val_SEQ0F).
{ok,[{ 'Button',3,true},
     { 'Button',4,false},
     { 'Button',5,true},
     { 'Button',6,true},
     { 'Button',7,false},
     { 'Button',8,true},
```

```

    {'Button',9,true},
    {'Button',10,false},
    {'Button',11,true},
    {'Button',12,true},
    {'Button',13,false},
    {'Button',14,true}}}
11> 'GUI':decode_part(Type_Key_SeqOf,hd(Val_SEQOF)).
{ok,{'Button',3,true}}
12> 'GUI':decode_part(Type_Key_Choice,Val_Choice).
{ok,{possibleActions,[{'Action',16,{'Button',17,true}}]}}
```

1.2.2 Selective Decode

This specialized decode decodes one single subtype of a constructed value. It is the fastest method to extract one sub value. The typical use of this decode is when one want to inspect, for instance a version number, to be able to decide what to do with the entire value. The result is returned as `{ok, Value}` or `{error, Reason}`.

How To Make It Work

The following steps are necessary:

- Write instructions in the configuration file. Including the name of a user function, the name of the ASN.1 specification and a notation that tells which part of the type will be decoded.
- Compile with the additional option `asn1config`. The compiler searches for a configuration file with the same name as the ASN.1 spec but with the extension `.asn1config`. In the same file you can provide configuration specs for exclusive decode as well. The generated Erlang module has the usual functionality for encode/decode preserved and the specialized decode functionality added.

User Interface

The only new user interface function is the one provided by the user in the configuration file. You can invoke that function by the `ModuleName:FunctionName` notation.

So, if you have the following spec `{selective_decode, {'ModuleName', [{selected_decode_Window, TypeList}]}}` in the con-fig file, you do the selective decode by `{ok, Result} = 'ModuleName':selected_decode_Window(EncodedBinary)`.

Writing a Selective Decode Instruction

It is possible to describe one or many selective decode functions in a configuration file, you have to use the following notation:

```

Selective_Decode_Instruction = {selective_decode, {Module_Name, Decode_Instructions}}.
Module_Name = atom()
Decode_Instructions = [Decode_Instruction]+
Decode_Instruction = {Selective_Decode_Function_Name, Type_List}
Selective_Decode_Function_Name = atom()
Type_List = [Top_Type|Element_List]
Element_List = Name|List_Selector
Name = atom()
```

1.2 Specialized Decodes

```
List_Selector = [integer()]
```

Observe that the instruction must be a valid Erlang term ended by a dot.

The `Module_Name` is the same as the name of the ASN.1 spec, but without the extension. A `Decode_Instruction` is a tuple with your chosen function name and the components from the top type that leads to the single type you want to decode. Notice that you have to choose a name of your function that will not be the same as any of the generated functions. The first element of the `Type_List` is the top type of the encoded message. In the `Element_List` it is followed by each of the component names that leads to selected type. Each of the names in the `Element_List` must be constructed types except the last name, which can be any type.

The `List_Selector` makes it possible to choose one of the encoded components in a SEQUENCE OF/ SET OF. It is also possible to go further in that component and pick a sub type of that to decode. So in the `Type_List`: `['Window', status, buttonList, [1], number]` the component `buttonList` has to be a SEQUENCE OF or SET OF type. In this example component number of the first of the encoded elements in the SEQUENCE OF `buttonList` is selected. This apply on the ASN.1 spec *above*.

Another Example

In this example we use the same ASN.1 spec as *above*. A valid selective decode instruction is:

```
{selective_decode,
  {'GUI',
    [{selected_decode_Window1,
      ['Window', status, buttonList,
        [1],
        number]},
    {selected_decode_Action,
      ['Action', handle, number]},
    {selected_decode_Window2,
      ['Window',
        status,
        actions,
        possibleActions,
        [1],
        handle, number]}]}.
```

The first `Decode_Instruction`, `{selected_decode_Window1, ['Window', status, buttonList, [1], number]}` is commented in the previous section. The instruction `{selected_decode_Action, ['Action', handle, number]}` picks the component `number` in the `handle` component of the type `Action`. If we have the value `ValAction = {'Action', 17, {'Button', 4711, false}}` the internal value 4711 should be picked by `selected_decode_Action`. In an Erlang terminal it looks like:

```
ValAction = {'Action', 17, {'Button', 4711, false}}.
{'Action', 17, {'Button', 4711, false}}
7> {ok, Bytes} = 'GUI':encode('Action', ValAction).
...
8> BinBytes = list_to_binary(Bytes).
<<48, 18, 2, 1, 17, 160, 13, 172, 11, 171, 9, 48, 7, 128, 2, 18, 103, 129, 1, 0>>
9> 'GUI':selected_decode_Action(BinBytes).
{ok, 4711}
10>
```

The third instruction, `['Window', status, actions, possibleActions, [1], handle, number]`, which is a little more complicated,

- starts with type *Window*.
- Picks component *status* of *Window* that is of type *Status*.
- Then takes component *actions* of type *Status*.
- Then *possibleActions* of the internal defined CHOICE type.
- Thereafter it goes into the first component of the SEQUENCE OF by [1]. That component is of type *Action*.
- The instruction next picks component *handle*.
- And finally component *number* of the type *Button*.

The following figures shows which components are in the TypeList ['Window', status, actions, possibleActions, [1], handle, number]. And which part of a message that will be decoded by selected_decode_Window2.

Figure 2.2: The elements specified in the config file for selective decode of a sub-value in a Window message

Figure 2.3: Figure symbolizes the bytes of a Window:status message. Only the marked element is decoded when selected_decode_Window2 is called.

With the following example you can examine that both selected_decode_Window2 and selected_decode_Window1 decodes the intended sub-value of the value Val

```
1> Val = {'Window',{status,{'Status',12,
    [{'Button',13,true},
    {'Button',14,false},
    {'Button',15,true},
    {'Button',16,false}],
    true,
    {possibleActions,[{'Action',17,{'Button',18,false}},
    {'Action',19,{'Button',20,true}},
    {'Action',21,{'Button',22,false}}]}}}
2> {ok,Bytes}='GUI':encode('Window',Val).
...
3> Bin = list_to_binary(Bytes).
<<161,101,128,1,12,161,32,48,6,128,1,13,129,1,255,48,6,128,1,14,129,1,0,48,6,128,1,15,129,...>>
4> 'GUI':selected_decode_Window1(Bin).
{ok,13}
5> 'GUI':selected_decode_Window2(Bin).
{ok,18}
```

Observe that the value feed into the selective decode functions must be a binary.

1.2.3 Performance

To give an indication on the possible performance gain using the specialized decodes, some measures have been performed. The relative figures in the outcome between selective, exclusive and complete decode (the normal case) depends on the structure of the type, the size of the message and on what level the selective and exclusive decodes are specified.

ASN.1 Specifications, Messages and Configuration

The specs *GUI* and **MEDIA-GATEWAY-CONTROL** was used in the test.

For the GUI spec the configuration looked like:

1.2 Specialized Decodes

```
{selective_decode,
  {'GUI',
    [{selected_decode_Window1,
      ['Window',
        status,buttonList,
        [1],
        number]}],
    {selected_decode_Window2,
      ['Window',
        status,
        actions,
        possibleActions,
        [1],
        handle,number]}]}].
{exclusive_decode,
  {'GUI',
    [{decode_Window_status_exclusive,
      ['Window',
        [{status,
          [{buttonList,parts},
            {actions,undecoded}}]}]}]}].
```

The MEDIA-GATEWAY-CONTROL configuration was:

```
{exclusive_decode,
  {'MEDIA-GATEWAY-CONTROL',
    [{decode_MegacoMessage_exclusive,
      ['MegacoMessage',
        [{authHeader,undecoded},
          {mess,
            [{mId,undecoded},
              {messageBody,undecoded}}]}]}]}].
{selective_decode,
  {'MEDIA-GATEWAY-CONTROL',
    [{decode_MegacoMessage_selective,
      ['MegacoMessage',mess,version]}]}].
```

The corresponding values were:

```
{'Window',{status,{'Status',12,
  [{'Button',13,true},
    {'Button',14,false},
    {'Button',15,true},
    {'Button',16,false},
    {'Button',13,true},
    {'Button',14,false},
    {'Button',15,true},
    {'Button',16,false},
    {'Button',13,true},
    {'Button',14,false},
    {'Button',15,true},
    {'Button',16,false}],
  true,
  {possibleActions,
    [{'Action',17,{'Button',18,false}},
      {'Action',19,{'Button',20,true}},
      {'Action',21,{'Button',22,false}},
```

```

        {'Action',17,{'Button',18,false}},
        {'Action',19,{'Button',20,true}},
        {'Action',21,{'Button',22,false}},
        {'Action',17,{'Button',18,false}},
        {'Action',19,{'Button',20,true}},
        {'Action',21,{'Button',22,false}},
        {'Action',17,{'Button',18,false}},
        {'Action',19,{'Button',20,true}},
        {'Action',21,{'Button',22,false}},
        {'Action',17,{'Button',18,false}},
        {'Action',19,{'Button',20,true}},
        {'Action',21,{'Button',22,false}},
        {'Action',17,{'Button',18,false}},
        {'Action',19,{'Button',20,true}},
        {'Action',21,{'Button',22,false}}]]]]}

{'MegacoMessage',asn1_NOVALUE,
 {'Message',1,
  {'ip4Address',
   {'IP4Address',[125,125,125,111],55555}},

decode/2	5889197	complete	GUI	100
----------	---------	----------	-----	-----

Table 2.1: Results of complete, exclusive and selective decode

Another interesting question is what the relation is between a complete decode, an exclusive decode followed by decode_part of the excluded parts and a selective decode followed by a complete decode. Some situations may be compared to this simulation, e.g. inspect a sub-value and later on look at the entire value. The following table shows figures from this test. The number of loops and time unit is the same as in the previous test.

<i>Actions</i>	<i>Function</i>	<i>Time(microseconds)</i>	<i>ASN.1 spec</i>	<i>% of time vs. complete decode</i>
complete	decode/2	4507457	MEDIA-GATEWAY-CONTROL	100

exclusive and decode_part	decode_-Window_-status_-exclusive/1	6249200	GUI	106.1

Table 2.2: Results of complete, exclusive + decode_part and selective + complete decodes

Other ASN.1 types and values can differ much from these figures. Therefore it is important that you, in every case where you intend to use either of these decodes, perform some tests that shows if you will benefit your purpose.

Comments

Generally speaking the gain of selective and exclusive decode in advance of complete decode is greater the bigger value and the less deep in the structure you have to decode. One should also prefer selective decode instead of exclusive decode if you are interested in just one single sub-value.

Another observation is that the exclusive decode followed by decode_part decodes is very attractive if the parts will be sent to different servers for decoding or if one in some cases not is interested in all parts.

1.2 Specialized Decodes

The fastest selective decode are when the decoded type is a primitive type and not so deep in the structure of the top type. The `selected_decode_window2` decodes a big constructed value, which explains why this operation is relatively slow.

It may vary from case to case which combination of selective/complete decode or exclusive/part decode is the fastest.

2 Reference Manual

The *Asn1* application contains modules with compile-time and run-time support for ASN.1.

asn1ct

Erlang module

The ASN.1 compiler takes an ASN.1 module as input and generates a corresponding Erlang module which can encode and decode the data-types specified. Alternatively the compiler takes a specification module (see below) specifying all input modules and generates one module with encode/decode functions. There are also some generic functions which can be used in during development of applications which handles ASN.1 data (encoded as BER or PER).

Note:

In R16, the options have been simplified. The back-end is chosen using one of the options `ber`, `per`, or `uper`. The options `optimize`, `nif`, and `driver` options are no longer necessary (and the ASN.1 compiler will print a warning if they are used). The options `ber_bin`, `per_bin`, and `uper_bin` options will still work, but will print a warning.

Another change in R16 is that the generated `encode/2` function (and `asn1rt:encode/3`) always returns a binary. The `encode/2` function for the BER back-end used to return an iolist.

Exports

```
compile(Asn1module) -> ok | {error, Reason}
```

```
compile(Asn1module, Options) -> ok | {error, Reason}
```

Types:

```
Asn1module = atom() | string()
Options = [Option | OldOption]
Option = ber | per | uper | der | compact_bit_string | legacy_bit_string
        | noobj | {n2n, EnumTypeName} | {outdir, Dir} | {i, IncludeDir} |
asn1config | undec_rest | no_ok_wrapper | {macro_name_prefix, Prefix} |
{record_name_prefix, Prefix} | verbose | warnings_as_errors
OldOption = ber | per
Reason = term()
Prefix = string()
```

Compiles the ASN.1 module `Asn1module` and generates an Erlang module `Asn1module.erl` with encode and decode functions for the types defined in `Asn1module`. For each ASN.1 value defined in the module an Erlang function which returns the value in Erlang representation is generated.

If `Asn1module` is a filename without extension first `".asn1"` is assumed, then `".asn"` and finally `".py"` (to be compatible with the old ASN.1 compiler). Of course `Asn1module` can be a full pathname (relative or absolute) including filename with (or without) extension.

If one wishes to compile a set of `Asn1` modules into one Erlang file with encode/decode functions one has to list all involved files in a configuration file. This configuration file must have a double extension `".set.asn"`, (`".asn"` can alternatively be `".asn1"` or `".py"`). The input files' names must be listed, within quotation marks (`"`), one at each row in the file. If the input files are `File1.asn`, `File2.asn` and `File3.asn` the configuration file shall look like:

```
File1.asn
```

```
File2.asn
File3.asn
```

The output files will in this case get their names from the configuration file. If the configuration file has the name `SetOfFiles.set.asn` the name of the output files will be `SetOfFiles.hrl`, `SetOfFiles.erl` and `SetOfFiles.asnldb`.

Sometimes in a system of ASN.1 modules there are different default tag modes, e.g. AUTOMATIC, IMPLICIT or EXPLICIT. The multi file compilation resolves the default tagging as if the modules were compiled separately.

Another unwanted effect that may occur in multi file compilation is name collisions. The compiler solves this problem in two ways: If the definitions are identical then the output module keeps only one definition with the original name. But if definitions only have same name and differs in the definition, then they will be renamed. The new names will be the definition name and the original module name concatenated.

If any name collision have occurred the compiler reports a "NOTICE: ..." message that tells if a definition was renamed, and the new name that must be used to encode/decode data.

Options is a list with options specific for the asn1 compiler and options that are applied to the Erlang compiler. The latter are those that not is recognized as asn1 specific. Available options are:

`ber` | `per` | `uper`

The encoding rule to be used. The supported encoding rules are BER (Basic Encoding Rules), PER aligned (Packed Encoding Rules) and PER unaligned. If the encoding rule option is omitted `ber` is the default.

The generated Erlang module always gets the same name as the ASN.1 module and as a consequence of this only one encoding rule per ASN.1 module can be used at runtime.

`der`

By this option the Distinguished Encoding Rules (DER) is chosen. DER is regarded as a specialized variant of the BER encoding rule, therefore the `der` option only makes sense together with the `ber` option. This option sometimes adds sorting and value checks when encoding, which implies a slower encoding. The decoding routines are the same as for `ber`.

`compact_bit_string`

The BIT STRING type will be decoded to the "compact notation". *This option is not recommended for new code.*

For details see *BIT STRING type section in the Users Guide*.

`legacy_bit_string`

The BIT STRING type will be decoded to the legacy format, i.e. a list of zeroes and ones. *This option is not recommended for new code.*

For details see *BIT STRING type section in the Users Guide*.

`{n2n, EnumTypeName}`

Tells the compiler to generate functions for conversion between names (as atoms) and numbers and vice versa for the `EnumTypeName` specified. There can be multiple occurrences of this option in order to specify several type names. The type names must be declared as ENUMERATIONS in the ASN.1 spec. If the `EnumTypeName` does not exist in the ASN.1 spec the compilation will stop with an error code. The generated conversion functions are named `name2num_EnumTypeName/1` and `num2name_EnumTypeName/1`.

`noobj`

Do not compile (i.e do not produce object code) the generated `.erl` file. If this option is omitted the generated Erlang module will be compiled.

`{i, IncludeDir}`

Adds `IncludeDir` to the search-path for `.asn1db` and `asn1` source files. The compiler tries to open a `.asn1db` file when a module imports definitions from another ASN.1 module. If no `.asn1db` file is found the `asn1` source file is parsed. Several `{i, IncludeDir}` can be given.

`{outdir, Dir}`

Specifies the directory `Dir` where all generated files shall be placed. If omitted the files are placed in the current directory.

`asn1config`

When one of the specialized decodes, exclusive or selective decode, is wanted one has to give instructions in a configuration file. The option `asn1config` enables specialized decodes and takes the configuration file, which has the same name as the ASN.1 spec but with extension `.asn1config`, in concern.

The instructions for exclusive decode must follow the *instruction and grammar in the User's Guide*.

You can also find the instructions for selective decode in the *User's Guide*.

`undec_rest`

A buffer that holds a message, being decoded may also have some following bytes. Now it is possible to get those following bytes returned together with the decoded value. If an `asn1` spec is compiled with this option a tuple `{ok, Value, Rest}` is returned. `Rest` may be a list or a binary. Earlier versions of the compiler ignored those following bytes.

`no_ok_wrapper`

If this option is given, the generated `encode/2` and `decode/2` functions will not wrap a successful return value in an `{ok, ...}` tuple. If any error occurs, there will be an exception.

`{macro_name_prefix, Prefix}`

All macro names generated by the compiler are prefixed with `Prefix`. This is useful when multiple protocols that contains macros with identical names are included in a single module.

`{record_name_prefix, Prefix}`

All record names generated by the compiler are prefixed with `Prefix`. This is useful when multiple protocols that contains records with identical names are included in a single module.

`verbose`

Causes more verbose information from the compiler describing what it is doing.

`warnings_as_errors`

Causes warnings to be treated as errors.

Any additional option that is applied will be passed to the final step when the generated `.erl` file is compiled.

The compiler generates the following files:

- `Asn1module.hrl` (if any SET or SEQUENCE is defined)
- `Asn1module.erl` the Erlang module with encode, decode and value functions.
- `Asn1module.asn1db` intermediate format used by the compiler when modules IMPORTS definitions from each other.

`encode(Module, Type, Value) -> {ok, Bytes} | {error, Reason}`

Types:

`Module = Type = atom()`

```

Value = term()
Bytes = binary()
Reason = term()

```

Encodes Value of Type defined in the ASN.1 module Module. To get as fast execution as possible the encode function only performs rudimentary tests that the input Value is a correct instance of Type. The length of strings is for example not always checked. Returns {ok, Bytes} if successful or {error, Reason} if an error occurred.

decode(Module, Type, Bytes) -> {ok, Value} | {error, Reason}

Types:

```

Module = Type = atom()
Value = Reason = term()
Bytes = binary()

```

Decodes Type from Module from the binary Bytes. Returns {ok, Value} if successful.

value(Module, Type) -> {ok, Value} | {error, Reason}

Types:

```

Module = Type = atom()
Value = term()
Reason = term()

```

Returns an Erlang term which is an example of a valid Erlang representation of a value of the ASN.1 type Type. The value is a random value and subsequent calls to this function will for most types return different values.

test(Module) -> ok | {error, Reason}

test(Module, Type | Options) -> ok | {error, Reason}

test(Module, Type, Value | Options) -> ok | {error, Reason}

Types:

```

Module = Type = atom()
Value = term()
Options = [{i, IncludeDir}]
Reason = term()

```

Performs a test of encode and decode of types in Module. The generated functions are called by this function. This function is useful during test to secure that the generated encode and decode functions and the general runtime support work as expected.

- test/1 iterates over all types in Module.
- test/2 tests type Type with a random value.
- test/3 tests type Type with Value.

Schematically the following happens for each type in the module:

```

{ok, Value} = asn1ct:value(Module, Type),
{ok, Bytes} = asn1ct:encode(Module, Type, Value),
{ok, Value} = asn1ct:decode(Module, Type, Bytes).

```

The `test` functions utilizes the `*.asn1db` files for all included modules. If they are located in a different directory than the current working directory, use the `include` option to add paths. This is only needed when automatically generating values. For static values using `Value` no options are needed.

asn1rt

Erlang module

This module is the interface module for the ASN.1 runtime support functions. To encode and decode ASN.1 types in runtime the functions in this module should be used.

Exports

`decode(Module,Type,Bytes) -> {ok,Value}|{error,Reason}`

Types:

```
Module = Type = atom()  
Value = Reason = term()  
Bytes = binary
```

Decodes `Type` from `Module` from the binary `Bytes`. Returns `{ok,Value}` if successful.

`encode(Module,Type,Value)-> {ok,Bytes} | {error,Reason}`

Types:

```
Module = Type = atom()  
Value = term()  
Bytes = binary  
Reason = term()
```

Encodes `Value` of `Type` defined in the ASN.1 module `Module`. Returns a possibly nested list of bytes and or binaries if successful. To get as fast execution as possible the encode function only performs rudimentary tests that the input `Value` is a correct instance of `Type`. The length of strings is for example not always checked.

Note:

Starting in R16, `Bytes` is always a binary.

`info(Module) -> {ok,Info} | {error,Reason}`

Types:

```
Module = atom()  
Info = list()  
Reason = term()
```

`info/1` returns the version of the `asn1` compiler that was used to compile the module. It also returns the compiler options that was used.

`utf8_binary_to_list(UTF8Binary) -> {ok,UnicodeList} | {error,Reason}`

Types:

```
UTF8Binary = binary()  
UnicodeList = [integer()]  
Reason = term()
```

`utf8_binary_to_list/1` Transforms a UTF8 encoded binary to a list of integers, where each integer represents one character as its unicode value. The function fails if the binary is not a properly encoded UTF8 string.

`utf8_list_to_binary(UnicodeList) -> {ok,UTF8Binary} | {error,Reason}`

Types:

```
UnicodeList = [integer()]  
UTF8Binary = binary()  
Reason = term()
```

`utf8_list_to_binary/1` Transforms a list of integers, where each integer represents one character as its unicode value, to a UTF8 encoded binary.
